# Approximation of the Permanent for Graphs of Density Less than $1 / 2$ is hard 

Elias Dahlhaus and Marek Karpinski<br>University of Bonn

Let $G=\left(V_{1} \cup V_{2}, E\right)$ be a bipartite graph with the two partitions $V_{1}$ and $V_{2}$. Multiple edges are not allowed. We assume that $V_{1}$ and $V_{2}$ have the same cardinality $n$. We call $G$ an $\alpha$-DENSE graph iff each vertex has a degree of at least $\alpha n$.

We call a probabilistic algorithm an $(\epsilon, \delta)$ - approximation algorithm, iff for given input $G, \epsilon, \delta$ it computes a number $Y$, such that the probabiltity that $Y$ is in between $\operatorname{per}(G) /(1+\epsilon)$ and $(1+\epsilon) \operatorname{per}(G)$ is at least $1-\delta$. Here $\operatorname{per}(G)$ is the number of perfect matchings of $G$ (also called the permanent)(see also [4]).
A. Broder[1] stated the following result (see also [4]):

Theorem 1: For 1/2-dense bipartite graphs there is an $(\epsilon, \delta)$-approximation algorithm for the permanent, polynomial in $n$.

Some additional results on approximation algorithms for the permanent are stated in [2].

We can show the following result which is in contrast to theorem 1 :
Theorem 2: Given any $\alpha<1 / 2$. Then an $(\epsilon, \delta)$-approximation algorithm for the permanent of any $\alpha$-dense bipartite graph, which is polynomial in $n$, implies the existence of a polynomial time $(\epsilon, \delta)$-approximation algorithm for any bipartite graph (approximation completeness).

Proof: The proof is very similar to the proof of matching completeness of the perfect matching problem for $\alpha$-dense graphs (see [3]. Given any bipartite graph $G=\left(V_{1} \cup V_{2}, E\right)$ We consider two copies $C_{i}=\left(W_{i} \cup W_{i}^{\prime}, E_{i}^{\prime}\right)$ of the complete bipartite graph with $m$ vertices per partition. We construct a new bipartite graph $G^{\prime}$ by joining each vertex of $W_{i}^{\prime}$ and each vertex of $V_{i}$ by an edge. It is easily seen that each perfect matching of $G^{\prime}$ is the disjoint union of a perfect matching of $C_{1}$, a perfect matching of $C_{2}$ and a perfect matching of $G$. Therefore $G$ has $k$ perfect matchings if and only if $G^{\prime}$ has $2(m!) k$ perfect matchings. Setting the ratio $m / n$ large enough $G^{\prime}$ is $\alpha$-dense.

Figure 1: The reduction from any bipartite graph to $\alpha$-dense graphs
