# Inapproximability of Dominating Set on Power Law Graphs (Revised Version) 

Mikael Gast* Mathias Hauptmann ${ }^{\dagger} \quad$ Marek Karpinski ${ }^{\ddagger}$

#### Abstract

We prove the first logarithmic lower bounds for the approximability of the Minimum Dominating Set problem for the case of connected ( $\alpha, \beta$ )-power law graphs for $\alpha$ being a size parameter and $\beta$ the power law exponent. We give also a best up to now upper approximation bound for this problem in the case of the parameters $\beta>2$. We develop also a new functional method for proving lower approximation bounds and display a sharp approximation phase transition area between approximability and inapproximability of the underlying problems. Our results depend on a method which could be also of independent interest.

Keywords: Approximation Algorithms, Inapproximability, Power Law Graphs, Combinatorial Optimization, Dominating Set

## 1 Introduction

The Minimum Dominating Set problem (Min-DS) asks for a minimum size set of vertices $D$ for a given graph $G$ such that each vertex in $G$ is either contained in $D$ or adjacent to some vertex in $D$. The Min-DS problem has asymptotically the same approximation upper and lower bounds as the Set Cover problem. It can be approximated within $(1-o(1)) \ln (n)$ by a greedy algorithm and, unless NP $\subseteq \operatorname{DTIME}\left(n^{O(\log \log n)}\right)$, there is no $(1-\varepsilon) \ln (n)$-approximation algorithm for MiN-DS for any $\varepsilon>0[8]$. Furthermore, Raz and Safra established an approximation lower bound of $c \cdot \ln (n)$ for some constant $c$ under the weaker assumption that $\mathrm{P} \neq \mathrm{NP}[20]$.

In this paper we give new approximation upper and lower bounds for Min-DS on power law graphs. $G$ is called a power law graph if the number of nodes of degree $i$ is proportional to $i^{-\beta}$, for some $\beta>0$. The parameter $\beta$ is called the power law exponent and determines the $\log -\log$ growth

[^0]rate of $G$. The Min-DS problem on power law graphs was originally introduced in the context of the sensor placement problems in massive social networks (cf. [7]).

Power law graphs (PLG) have been used in modeling and analyzing the real-world networks like the graphs of the Internet and the World Wide Web (WWW), peer-to-peer networks, mobile call networks, protein-protein interaction networks, gene regulatory networks, food webs and various social networks. Typically, the power law exponent of these real-world networks lies within the range $2<\beta<3$ (e.g. $\beta=2.38$ for the WWW [5], $\beta=2.4$ for protein-protein interaction networks [13]). There also exist examples of real-world networks with a power law exponent $\beta \leq 2$ or $\beta \geq 3$, e.g. for distributional food webs $(\beta=1.05,[18])$, statistical investigations of book sales in the US $(\beta=3.51,[12,19])$ and human contact networks $(\beta=3.4,[17])$.

A number of different random graph models were proposed in order to capture the topological properties of real-world networks and to analyze these graphs on the basis of a so called null-model (see $[3,15,16,1,2,6,4]$ ). On this basis, two different types of models have been introduced. The evolving models define a random process where one node at a time is added and connected to the existing graph in a random fashion-and thus are aiming to describe how power laws arise. The static models start from a given power law degree sequence as an input and then perform a random selection from the space of graphs with this degree sequence. The most prominent examples of the two types are the preferential attachment model described by Barabási and Albert [3], and the ACL model introduced by Aiello, Chung, and $\mathrm{Lu}[1,2]$.

In this paper, we consider the power law model $(\alpha, \beta)$-PLG due to Aiello, Chung, and Lu (also called the ACL model). A (multi-)graph $G$ with maximum degree $\Delta$ is called an ( $\alpha, \beta$ )-PLG with size parameter $\alpha$ and a power law exponent $\beta$, if for each $i \leq \Delta=\left\lfloor e^{\alpha / \beta}\right\rfloor$, the number of nodes of degree $i$ is equal to $\left\lfloor e^{\alpha} / i^{\beta}\right\rfloor$.

## 2 Previous Results

Ferrante, Pandurangan, and Park [9] have shown the NP-hardness of Min-DS on simple disconnected $(\alpha, \beta)$-PLG for $\beta>0$. In [21] it was shown that Min-DS on $(\alpha, \beta)$-PLG is in APX for $\beta>2$. Furthermore, for $\beta>1$, APX-hardness was shown and explicit constant approximation lower bounds were given, namely $1+\frac{1}{390\left(2 \zeta(\beta) 3^{\beta}-1\right)}$ on $(\alpha, \beta)$-PLG multigraphs and $1+\frac{1}{3120 \zeta(\beta) 3^{\beta}}$ on simple $(\alpha, \beta)$-PLG.

Eubank et al. [7] studied a relaxed version of Min-DS: In the ( $1-\varepsilon$ )-Min-DS problem the requirement is to dominate at least an $(1-\varepsilon)$-fraction of the vertices. They show that for every $\varepsilon>0$, the $(1-\varepsilon)$-Min-DS problem on bipartite random PLG admits a PTAS.

## 3 Our Results

In this paper, we give the first logarithmic lower approximation bounds for Min-DS on ( $\alpha, \beta$ )-PLG for the case $\beta \leq 2$. The best up to now approximation lower bound was a constant bound [21]. We show that in this case, unless NP $\subseteq \operatorname{DTIME}\left(n^{O(\log \log n)}\right)$, Min-DS on connected $(\alpha, \beta)$-PLG cannot be approximated within an approximation ratio $\Omega(\ln (n))$. Thus our lower approximation bound is almost tight. We also give improved approximation upper bounds for the case $\beta>2$ and show that in this case, Min-DS on ( $\alpha, \beta$ )-PLG can be approximated within some constant approximation ratio $R_{\beta}$ which converges to 1 as $\beta \rightarrow \infty$.

Then we take a very precise look at the phase transition point at $\beta=2$. We consider a case when $\beta=2+1 / f(n)$ is a function of the size of the graph. Here, $n$ denotes the number of vertices of the PLG, and $f$ is a monotone increasing unbounded function. Surprisingly, we obtain a very sharp phase transition result, between approximability and inapproximability areas depending on the order of magnitude of the function $f$. We show that when $f(n)=o(\log n)$, Min-DS on $(\alpha, 2+1 / f(n))$-PLG is still in APX. On the other hand, we give a logarithmic approximation lower bound for the case when $f(n)=\omega(\log n)$.

Our approximation lower bounds are based on a direct approximate reduction from the SET Cover problem to the Min-DS problem combined with an embedding of the resulting graph instances into ( $\alpha, \beta$ )-PLG. Our constructions rely on precise estimates of sizes of node intervals in $(\alpha, \beta)$-PLG and on the available node degree inside these intervals. Table 1 summarizes our main results in lower and upper approximation bounds for Min-DS on ( $\alpha, \beta$ )-PLG.

| Power Law Exponent | Approx. Lower Bound |
| :---: | :---: |
| $0<\beta<1$ | $\Omega\left(\ln (n)-\ln \left(\frac{1}{1-\beta}\right)\right)$ |
| $\beta=1$ | $\Omega(\ln (n))$ |
| $1<\beta<2$ | $\Omega(\ln (n)-\ln (\zeta(\beta)))$ |
| $\beta=2$ | $\Omega(\ln (n)-\ln (\zeta(\beta)))$ |
| $\beta=2+\frac{1}{f(n)}, f(n)=\omega(\log n)$ | $\Omega(\ln (n)-\ln (\zeta(\beta)))$ |

| Power Law Exponent | Approx. Upper Bound |
| :---: | :---: |
| $\beta=2+\frac{1}{f(n)}, f(n)=o(\log n)$ | APX |
| $2<\beta \leq 2.729$ | $\frac{\zeta(\beta)-1}{\zeta(\beta)-\sum_{j=1}^{d-1} j^{-\beta}}$ |
| $\beta>2.729$ | $\frac{\zeta(\beta-1)-2 \zeta(\beta)}{\zeta(\beta-1)-2}$ |

Table 1: Summary of the main results: Approximation lower bounds and approximation upper bounds for Min-DS on $(\alpha, \beta)$-PLG for certain ranges of the parameter $\beta$. The precise choice of the parameter $d$ is described in Theorem 4.

## 4 Organization of the Paper

In Section 5, we are giving an outline of the proof methods and the simulating constructions on which our reductions are based. In Section 6, we use the original reduction of Feige [8] from 5Occ-Max-E3-Sat (5 Occurrence Maximum E3-Sat) to the Set Cover problem and the reduction from the Set Cover to Min-DS. As a result of this section, we obtain sufficient information about the degree distribution of the resulting Min-DS instances $G_{U, \mathcal{S}}$. In Section 7 we give new lower bounds on the approximability of Min-DS on ( $\alpha, \beta$ )-PLG. The case $0<\beta<1$ is treated in Section 7.1, based on a precise rounding error analysis for the terms that determine the lower approximation bound. A similar analysis is used for the case $\beta=1$ in Section 7.2. The Section 7.3 deals with the case $1<\beta \leq 2$. Especially, we describe how to rescale the degree distribution of instances $G_{U, \mathcal{S}}$ in order to embed them into an $(\alpha, \beta)$-PLG. In Section 8 we present new upper bounds for the case of $\beta>2$ and provide a detailed comparison of the previous and new upper bounds in terms of the parameter $\beta$. In Section 9 we consider the functional case when $\beta_{f}=2+\frac{1}{f(n)}$ is a function of the graph size $n$ which converges from above to 2 .

## 5 Outline of the Method

We are going to give an outline of our methods and the underlying constructions. In order to obtain logarithmic approximation lower bounds for the Min-DS problem on $(\alpha, \beta)$-power law graphs, we construct reductions from Min-DS in graphs, the problem which is basically as hard to approximate as the Set Cover problem. It is well known (cf. [14]) that Set Cover instances ( $U, \mathcal{S}$ ) with universe $U$ and set system $\mathcal{S}$ can be translated into instances $G_{U, \mathcal{S}}$ of Min-DS in graphs, where $G_{U, \mathcal{S}}$ contains a vertex for every element of $U$ and vertices for the sets $S \in \mathcal{S}$. Element vertices are connected to set vertices of those sets in which they are contained, and two set vertices are connected by an edge if and only if the two sets have a non-empty intersection.

Our reductions map those graphs $G_{U, \mathcal{S}}$ which are stemming from the Set Cover instances $(U, \mathcal{S})$ to $(\alpha, \beta)$-power law graphs $\mathcal{G}_{\alpha, \beta}$. In this construction, nodes of the graph $G_{U, \mathcal{S}}$ are connected to a set $\Gamma$ of degree 2 nodes, and those are again connected to the rest of the graph. The set $\Gamma$ enforces any reasonable dominating set in $\mathcal{G}_{\alpha, \beta}$ to contain a dominating set of the graph $G_{U, \mathcal{S}}$. Another important property of our constructions is that the residual graph $\mathcal{G}_{\alpha, \beta} \backslash\left(G_{U, \mathcal{S}} \cup \Gamma\right)$ contains a sufficiently small set $X$ of vertices which dominate every node in $\mathcal{G}_{\alpha, \beta} \backslash G_{U, \mathcal{S}}$. It is precisely this property which enables us to obtain logarithmic lower bounds (instead of the previously known constant lower bounds) for the approximability of Min-DS in $(\alpha, \beta)$-PLG.

The crucial point in our construction is the implementation of the power law distribution. Therefore we need to know the degree distribution in the graph $G_{U, \mathcal{S}}$. In Section 6 we use the original construction from [8], and obtain upper and lower bounds for the degrees of nodes in the graph $G_{U, \mathcal{S}}$, where $(U, \mathcal{S})$ is a Set Cover instance. We apply our construction only to those SEt

Cover instances $(U, \mathcal{S})=F_{S C}(\varphi)$ where $\varphi$ is a 5Occ-MAX-E3-SAT instance and $F_{S C}$ is Feige's reduction from [8]. We show that the Min-DS instances $G_{U, \mathcal{S}}$ have the following property: There exist constants $0<a<b<1$ such that for every $(U, \mathcal{S})$ with $(U, \mathcal{S})=F_{S C}(\varphi)$, the node degrees of all vertices in $G_{U, \mathcal{S}}$ are contained in the interval $\left[N^{a}, N^{b}\right]$, where $N$ is the number of vertices of the graph $G_{U, \mathcal{S}}$.

Intervals and Volumes. In the following, we introduce some notions connected to the intervals of nodes inside an $(\alpha, \beta)$-power law graph and of the volume of such intervals. Let $\mathcal{G}_{\alpha, \beta}=(V, E)$ be an $(\alpha, \beta)$-power law graph with $n$ nodes. Thus, $n=\sum_{i=1}^{\Delta}\left\lfloor\frac{e^{\alpha}}{i^{\beta}}\right\rfloor$, where $\Delta=\left\lfloor e^{\alpha / \beta}\right\rfloor$ is the maximum degree of $\mathcal{G}_{\alpha, \beta}$. Let $m=|E|=\frac{1}{2} \sum_{i=1}^{\Delta}\left\lfloor\frac{e^{\alpha}}{i^{\beta}}\right\rfloor$ be the number of edges of $\mathcal{G}_{\alpha, \beta}$. According to [1, 2], the parameters $n, m, \alpha$ and $\beta$ are related roughly as follows:

$$
n \approx\left\{\begin{array} { l l } 
{ \zeta ( \beta ) e ^ { \alpha } } & { \text { if } \beta > 1 } \\
{ \alpha e ^ { \alpha } } & { \text { if } \beta = 1 } \\
{ \frac { e ^ { \frac { \alpha } { \beta } } } { 1 - \beta } } & { \text { if } 0 < \beta < 1 }
\end{array} \quad \text { and } \quad m \approx \left\{\begin{array}{ll}
\frac{1}{2} \zeta(\beta-1) e^{\alpha} & \text { if } \beta>2 \\
\frac{1}{4} \alpha e^{\alpha} & \text { if } \beta=2 \\
\frac{1}{2} \frac{e^{\frac{2 \alpha}{\beta}}}{2-\beta} & \text { if } 0<\beta<2
\end{array}\right.\right.
$$

An interval of nodes in $\mathcal{G}_{\alpha, \beta}$ is a set $[a, b]=\{v \in V \mid a \leq \operatorname{deg}(v) \leq b\}$, where $1 \leq a \leq b \leq \Delta=$ $\left\lfloor e^{\alpha / \beta}\right\rfloor$. Let $|[a, b]|$ be the number of nodes inside the interval $[a, b]$. The volume of an interval $[a, b]$ is defined as $\operatorname{vol}([a, b])=\sum_{j=a}^{b}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j$, i.e. the sum of node degrees of nodes inside the interval.

Embedding Technique. We are going now to construct a map which embeds every graph $G_{U, \mathcal{S}}$ (where $(U, \mathcal{S})$ is a SEt Cover instance from Feige's hardness result) into an $(\alpha, \beta)$-PLG $\mathcal{G}_{\alpha, \beta}$. Let $G_{U, \mathcal{S}}=\left(V_{U, \mathcal{S}}, E_{U, \mathcal{S}}\right)$ with $\left|V_{U, \mathcal{S}}\right|=N$. The graphs $G_{U, \mathcal{S}}$ have the following property: There exist constants $0<a<b<1$ such that for all $v \in V_{U, \mathcal{S}}, N^{a} \leq \operatorname{deg}_{U, \mathcal{S}}(v) \leq N^{b}$. The power law graph $\mathcal{G}_{\alpha, \beta}=\left(V_{\alpha, \beta}, E_{\alpha, \beta}\right)$ has the vertex set $V_{\alpha, \beta}=V_{U, \mathcal{S}} \cup X \cup \Gamma \cup V_{1} \cup W$. The set $X$ is a subset of the node interval $[x \Delta, y \Delta]=\left\{v \in V_{\alpha, \beta} \mid x \Delta \leq \operatorname{deg}_{\alpha, \beta}(v) \leq y \Delta\right\}$. $X$ is the set of dominating nodes, $V_{1}$ is the set of degree 1 nodes and $W$ the set of remaining nodes which is needed to implement the power law distribution. The power law graph $\mathcal{G}_{\alpha, \beta}$ is constructed in such a way that each node in $V_{U, \mathcal{S}}$ has precisely one neighbor in $\Gamma \subseteq W$, and every $u \in \Gamma$ has precisely one neighbor in $V_{U, \mathcal{S}}$. Furthermore, each node $w \in W$ is adjacent to precisely one node in $X$ and every degree 1 node is adjacent to a node in $X$, whereas each $v \in X$ has at least one degree 1 neighbor. From this construction it follows that the set $X$ dominates every vertex in $W$ and all the degree 1 nodes in $V_{1}$. (cf. Figure 1). During the construction of the graph $\mathcal{G}_{\alpha, \beta}$, we keep track of the residual degrees $\operatorname{deg}_{r}(v)$ of nodes in $X \cup W \cup V_{1}$.

The algorithm ConstructPLG on page 7 gets as an input the graph $G_{U, \mathcal{S}}$ for a given Set Cover instance $(U, \mathcal{S})$ and constructs the associated power law graph $\mathcal{G}_{\alpha, \beta}$. The procedure Fill_Wheel gets as an input a set of nodes $V$ with residual degrees $\operatorname{deg}_{r}(v)>0, \forall v \in V$ and generates the missing

Figure 1: The main construction for the embedding of a Min-DS (SET Cover) instance $G_{U, \mathcal{S}}$ into a $(\alpha, \beta)$-PLG. In the resulting graph the nodes $\bullet \in X$ are dominating the sets $W \cup V_{1}$, separating the dominating set in $G_{U, \mathcal{S}}$ from the dominating set in $\mathcal{G}_{\alpha, \beta} \backslash G_{U, \mathcal{S}}$.
edges degree-wise in a cyclic order. Let $v_{j, 1}, \ldots, v_{j, n_{j}}$ be the nodes of degree $\operatorname{deg}_{\alpha, \beta}\left(v_{j, l}\right)=j$ in the set $V$, then the following invariant will be maintained. In every stage of the construction, for every $j \in\{1, \ldots, \Delta\}, \operatorname{deg}_{r}\left(v_{j, 1}\right) \leq \cdots \leq \operatorname{deg}_{r}\left(v_{j, n_{j}}\right)$ and $\operatorname{deg}_{r}\left(v_{j, n_{j}}\right)-\operatorname{deg}_{r}\left(v_{j, 1}\right) \leq 1$. The procedure Fill_Wheel is described in detail in [11]. Figure 2 shows how the node intervals with the same

Figure 2: Procedure Fill_Wheel realizes the residual degrees on the wheel nodes in $W$ and $X$.
residual degree are filled and how the case is treated when the number of nodes contained in such an interval is odd. The set $X \subseteq[x \Delta, y \Delta]$ and the parameters $x \Delta$ and $y \Delta$ of the construction are chosen such that the volume $\operatorname{vol}([x \Delta, y \Delta])=\sum_{j=x \Delta}^{\Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j$ minimally exceeds the number of nodes in $V_{\alpha, \beta} \backslash X$. Thus, some nodes $v \in X$ might have residual degree $>0$. In this case, Fill_Wheel $(X)$ is used to reduce the residual degree of these nodes to 0 . Furthermore, each node $w \in W$ is connected to the set $X$ by a single edge. Since the residual degrees of nodes $w \in W$ are within the interval $[3, \Delta]$, Fill_Wheel $(W)$ is used to reduce the residual degree of nodes $w \in W$ to 0.

In the subsequent sections, we will show how to choose the parameters $x$ and $y$ of the construc-

```
Algorithm 1: ConstructPLG
    Input: \(G_{U, \mathcal{S}}=\left(V_{U, \mathcal{S}}, E_{U, \mathcal{S}}\right)\) with \(\left|V_{U, \mathcal{S}}\right|=N\).
    Output: Power law graph \(\mathcal{G}_{\alpha, \beta}=\left(V_{\alpha, \beta}, E_{\alpha, \beta}\right)\) with \(V_{\alpha, \beta}=V_{U, \mathcal{S}} \cup X \cup W \cup V_{1} \cup V_{2}\),
                    \(\left|V_{\alpha, \beta}\right|=n\) and \(E_{U, \mathcal{S}} \subseteq E_{\alpha, \beta}\).

    foreach \(w \in W\) do
        choose \(v \in X\) with maximum \(\operatorname{deg}_{r}(v)>0\) and set \(E_{\alpha, \beta}:=E_{\alpha, \beta} \cup\{w, v\} ;\)
        update \(\operatorname{deg}_{r}(w)\) and \(\operatorname{deg}_{r}(v)\);
    Fill_Wheel \((W)\); /* realizes residual degrees on \(W\) and \(X\) */
    Fill_Wheel \((X)\);
    return \(\mathcal{G}_{\alpha, \beta}=\left(V_{\alpha, \beta}, E_{\alpha, \beta}\right)\);
```

tion depending on the power law exponent $\beta$ in such a way that the set $X$ becomes sufficiently small. Hence any dominating set $D^{\prime}$ in $\mathcal{G}_{\alpha, \beta}$ can be efficiently transformed into a dominating set $D$ of size $|D| \leq\left|D^{\prime}\right|$ such that $D=D_{U, \mathcal{S}} \cup X$, where $D_{U, \mathcal{S}} \subseteq V_{U, \mathcal{S}}$ is a dominating set of $G_{U, \mathcal{S}}$.

## 6 Node Degrees and Lower Bound for Set Cover

In order to go on with our proof we need the following constructions. We start with Feige's [8] logarithmic lower bound for the approximability of the Set Cover problem. For each Set Cover instance $(U, \mathcal{S})$ we embed the associated Min-DS instance $G_{U, \mathcal{S}}$ into an $(\alpha, \beta)$-PLG $\mathcal{G}_{\alpha, \beta}$. In order to implement the power law node-degree distribution, we need to know the degree distribution of the graph $G_{U, \mathcal{S}}$. Therefore we briefly review the construction from [8]. This construction is based on a $k$-prover proof system for the problem 5Occ-MAX-E3-SAt. Consider a 3CNF formula $\varphi$ with $n$ variables such that each variable occurs at most 5 times in $\varphi$. One can assume that either the formula is satisfiable, or no assignment satisfies more than an $\varepsilon$ fraction of the clauses simultaneously. The $k$-prover proof system works as follows: It chooses $k$ codewords of length $l=\Theta(\log \log n)$, weight $l / 2$ and pairwise Hamming distance $\geq l / 3$. The verifier picks $l$ clauses $C_{1}, \ldots, C_{l}$ from $\varphi$ independently uniformly at random. Independently, from each such clause $C_{i}$ it picks one variable $x_{i}$ of $C_{i}$ uniformly at random. For each $1 \leq i \leq k$, the verifier sends to the prover
$i$ those $l / 2$ clauses $C_{j}$ for which the associated bit of prover $i$ 's codeword is 1 and those $l / 2$ variables $x_{j}$ for which the associated bit of prover $i$ 's codeword is 0 . The provers return their answers, and based on this the verifier determines its output. The construction of the associated Set Cover instances makes use of some combinatorial building blocks called partition systems.

Following [8], we define a partition system $B(m, L, k, d)$ to consist of a ground set $B$ of cardinality $|B|=m$ and $L$ partitions $p_{1}, \ldots, p_{L}$ of $B$ into $k$ disjoint subsets $p_{j, h} \subset B$. The defining property of these partition systems is that each cover of $B$ by subsets $p_{j, h}$ which uses sets from pairwise different partitions must consist of at least $d$ subsets. [8] gives a randomized construction of such partition systems with $L \approx(\log m)^{c}, k$ being any number smaller than $\ln (m / 3) \cdot \ln \ln (m)$ and $d=(1-f(k)) \cdot k \cdot \ln (m)$ with some function $f(k)$ with $f(k) \longrightarrow 0$ as $k \longrightarrow \infty$. That construction yields partitions for which with high probability all the sets have the same size. We show that the same result is obtained by making use of random permutations. But now, for each partition $p_{j}$, the sets $p_{j, h}$ always have the same size $m / k$ (provided $k \mid m$ ). Namely, choose a random permutation $\pi_{j} \in_{R} S_{m}$ and let $p_{j, h}=\left\{\pi_{j}((h-1) m / k+1), \ldots, \pi_{j}(k \cdot m / k)\right\}$. Suppose now we cover $B$ with $d$ subsets $p_{j_{1}, h_{1}}, \ldots, p_{j_{d}, h_{d}}$ from pairwise different partitions. Then for a given point $v \in B$, the probability that $v$ is covered by at least one of them is
$P$ (point $v \in B$ is covered by at least one of these $d$ sets)

$$
\begin{aligned}
& =1-\prod_{i=1}^{d} P\left(v \text { is not in position } 1, \ldots, m / k \text { in permutation } \pi_{j}\right)=1-\left(\frac{\binom{m-1}{m / k} \cdot\left(\frac{m}{k}\right)!\cdot\left(m-\frac{m}{k}\right)!}{m!}\right)^{d} \\
& =1-\left(\frac{(m-1)!\cdot\left(m-\frac{m}{k}\right)!}{\left(m-1-\frac{m}{k}\right)!\cdot m!}\right)^{d}=1-\left(\frac{m \cdot\left(1-\frac{1}{k}\right)}{m}\right)^{d}=1-\left(1-\frac{1}{k}\right)^{d} .
\end{aligned}
$$

This is precisely the property of the randomized construction which has been used in [8] in the analysis of the construction. So from now on we assume that all sets of a partition $p_{j}$ have the same size $m / k$.

Resulting Set Cover Instances ([8]). For a given 5Occ-MAX-E3-Sat formula $\varphi$ with $n$ variables and the property that either $\varphi$ is satisfiable or no assignment satisfies more than an $\varepsilon$ fraction of the clauses, a Set Cover instance $(U, \mathcal{S})$ is constructed as follows:

- $\mathcal{R}$ is the set of random strings used by the verifier in the $k$-Prover Proof System. The number of random strings is $|\mathcal{R}|=R=(5 n)^{l}$.
- $|U|=m R$ with $m=(5 n)^{\frac{2 l}{\varepsilon}}$, hence $|U|=(5 n)^{l(1+2 / \varepsilon)}$
- For each $r \in \mathcal{R}, B_{r}(m, L, k, d)$ is a partition system with $L=2^{l}$.
- $Q=n^{1 / 2} \cdot\left(\frac{5 n}{3}\right)^{1 / 2}$ is the number of different queries the verifier may ask to a prover.
- $\mathcal{S}$ contains for every triple ( $q, a, i$ ) a set $S_{q, a, i}$, where $q$ is a query, $i$ is (the index of) a prover and $a$ is the prover's answer. The set $S_{q, a, i}$ is defined as $S_{q, a, i}=\bigcup_{r:(q, i) \in r} B\left(r, a_{r}, i\right)$.

Hence the number of sets in $\mathcal{S}$ is $Q \cdot k$, and each set is of cardinality $\sqrt{R} \cdot m / k$. We have to give an estimate for the number of sets in which a point (an element of $U$ ) occurs. For each prover $i$, for each query $q$, each point in $B_{r}$ with $\left|B_{r}\right|=m$ occurs in $2^{l}$ sets $S_{q, a, i}$. Hence the total degree of points (the number of occurrences of this point in sets) is $2^{l} \cdot Q$.

From Set Cover to Dominating Set. Let $(U, \mathcal{S})$ denote a Set Cover instance with $U=$ $\left\{u_{1}, \ldots, u_{|U|}\right\}$ and $\mathcal{S}=\left\{S_{1}, \ldots, S_{|\mathcal{S}|}\right\}$. Let $G_{U, \mathcal{S}}$ be the undirected graph with set of vertices $V_{U, \mathcal{S}}=U \cup \mathcal{S}$ and set of edges $E_{U, \mathcal{S}}=\left\{\left\{S_{i}, u_{j}\right\} \mid u_{j} \in S_{i}\right\} \cup\left\{\left\{S_{j}, S_{l}\right\} \mid S_{j} \cap S_{l} \neq \emptyset\right\}$. We observe that each set cover $\mathcal{C} \subseteq \mathcal{S}$ is a dominating set in $G_{U, \mathcal{S}}$. On the other hand, let $D \subseteq V_{U, \mathcal{S}}$ be a dominating set in $G_{U, \mathcal{S}}$ with $D=D_{U} \cup D_{\mathcal{S}}, D_{U}=D \cap U$ and $D_{\mathcal{S}}=D \cap \mathcal{S}$. If we replace each $u_{i} \in D_{U}$ by an arbitrary set $S_{j}$ with $u_{i} \in S_{j}$, the resulting set $D^{\prime}$ is a dominating set with $D_{\mathcal{S}} \subseteq D^{\prime} \subseteq \mathcal{S}$ and $\left|D^{\prime}\right| \leq|D|$. In this way dominating sets in $G_{U, \mathcal{S}}$ correspond to set covers $\mathcal{C}$ for $(U, \mathcal{S})$.

In the construction in [8], the parameter $l$ satisfies $l=\Theta(\log \log n)$. If $N_{0}=|U|+|\mathcal{S}|$ is the number of nodes of $G_{U, \mathcal{S}}$, then (up to logarithmic factors), $N_{0} \approx n^{l}+n^{l(1+2 / \varepsilon)}$, the degree of element nodes $u \in U$ is $\approx n^{l}$, each set contains $n^{l(1 / 2+2 / \varepsilon)}$ elements and there are $\approx n^{l}$ sets. The degree of set nodes in $G_{U, \mathcal{S}}$ is bounded by the sum of the cardinality of that set and the number of sets in the instance $(U, \mathcal{S})$, which is $\approx n^{l(1 / 2+2 / \varepsilon)}$. Hence we obtain the following result we will use in the sequel.

Lemma 1. Let $F_{S C}$ denote Feige's reduction from 5Occ-MAx-E3-SAT to the SEt Cover problem, and for a given SET Cover instance $(U, \mathcal{S})=F_{S C}(\varphi)$ let $G_{U, \mathcal{S}}$ be the associated MIN-DS instance as described above. If $N_{0}$ is the number of nodes of $G_{U, \mathcal{S}}$, then for every node $v$ in $G_{U, \mathcal{S}}$, the node degree of $v$ in $G_{U, \mathcal{S}}$ satisfies $N_{0}^{a} \leq \operatorname{deg}_{U, \mathcal{S}}(v) \leq N_{0}^{b}$, where $0<a<b<1$ and $b=(1+o(1)) \cdot \frac{1 / 2+2 / \varepsilon}{1+2 / \varepsilon}=$ $(1+o(1)) \cdot \frac{\varepsilon+4}{2 \varepsilon+4}$.

In the next section we consider approximation lower bounds for the values of $\beta$ satisfying $0<\beta \leq 2$.

## 7 New Lower Bounds for $0<\beta \leq 2$

We will now describe our new logarithmic lower bounds for approximability of the Min-DS problem in $(\alpha, \beta)$-PLG. We distinguish several cases depending on the range of the parameter $\beta$. For the cases $0<\beta<1,1<\beta<2$ and $\beta=2$ our construction involves rescaling of the instances $G_{U, \mathcal{S}}$, which has the effect of shifting the degree interval $\left[N^{a}, N^{b}\right]$ towards the left end of the full interval $[1, \Delta]$. It turns out that for the case $\beta=1$ we can omit the scaling and directly implement the power law distribution.

Bounds on Optimums in $G_{U, \mathcal{S}}$. Let $(U, \mathcal{S})$ be an instance of the Set Cover problem which is an image $(U, \mathcal{S})=F_{S C}(\varphi)$ of some 5Occ-MAX-E3-SAT instance $\varphi$ under Feige's reduction $F_{S C}$. Suppose the number of nodes of $G_{U, \mathcal{S}}$ is $N_{0}$. Let $\operatorname{OPT}\left(G_{U, \mathcal{S}}\right)$ denote a minimum cardinality dominating set of $G_{U, \mathcal{S}}$. Then
$\left|\mathrm{OPT}\left(G_{U, \mathcal{S}}\right)\right| \leq k \cdot N_{0}^{\frac{\varepsilon}{2+\varepsilon}} \quad$ or $\quad\left|\mathrm{OPT}\left(G_{U, \mathcal{S}}\right)\right| \geq(1-\varepsilon) \cdot k \cdot N_{0}^{\frac{\varepsilon}{2+\varepsilon}} \cdot \frac{\varepsilon}{2+\varepsilon} \cdot\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} \cdot\left(\ln \left(N_{0}\right)-O(1)\right)$,
where $k$ is the number of provers in Feige's $k$-prover proof system. Recall that the 3CNF formula $\varphi$ with $F_{S C}(\varphi)=(U, \mathcal{S})$ is either satisfiable, or no assignment satisfies more than an $\varepsilon$ fraction of its clauses. Furthermore, as a result of Lemma 1, the node degrees in $G_{U, \mathcal{S}}$ are contained in the interval $\left[N_{0}^{a}, N_{0}^{b}\right]$ with $0<a<b<1$ being constant.

Scaling. In the three cases $0<\beta<1,1<\beta<2$ and $\beta=2$, it turns out that we have to rescale the degrees of nodes in $G_{U, \mathcal{S}}$ in order shift the interval associated to $G_{U, \mathcal{S}}$ towards the left end of the full interval. This will yield a better lower bound for the size of a dominating set in $G_{U, \mathcal{S}}$ and prevents overlapping of the intervals $\left[N^{a}, N^{b}\right]$ and $[x \Delta, y \Delta]$. For this purpose, we replace $G_{U, \mathcal{S}}$ by the graph $G_{U, \mathcal{S}}^{d}$ which consists of $N_{0}^{d-1}$ disjoint copies of the graph $G_{U, \mathcal{S}}$ (cf. Figure 3). Here, $d$ is a

Figure 3: Scaling by replacing the original graph $G_{U, \mathcal{S}}$ by $N_{0}^{d-1}$ disjoint copies in order to shift the occupied degree set towards the left end of the full interval.
parameter of our construction. The graph $G_{U, \mathcal{S}}^{d}$ has the following properties: The number of nodes is $N:=N_{0}^{d}$. The node degrees are contained in the interval $\left[N^{a / d}, N^{b / d}\right]$. Let OPT $\left(G_{U, \mathcal{S}}^{d}\right)$ denote
an optimum dominating set of $G_{U, \mathcal{S}}$. Then

$$
\begin{aligned}
\left|\mathrm{OPT}\left(G_{U, \mathcal{S}}^{d}\right)\right| & \leq N^{\frac{d-1}{d}} k N^{\frac{1}{d} \frac{\varepsilon}{2+\varepsilon}}=k N^{\frac{1}{d}\left(d-1+\frac{\varepsilon}{2+\varepsilon}\right)} \text { or } \\
\left|\operatorname{OPT}\left(G_{U, \mathcal{S}}^{d}\right)\right| & \geq(1-\varepsilon) k N^{\frac{1}{d} \frac{\varepsilon}{2+\varepsilon}} \frac{\varepsilon}{2+\varepsilon}\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}}\left(\ln \left(N^{\frac{1}{d}}\right)-O(1)\right) N^{\frac{d-1}{d}} \\
& =k \frac{\varepsilon(1-\varepsilon)}{2+\varepsilon}\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} N^{\frac{1}{d}\left(d-1+\frac{\varepsilon}{2+\varepsilon}\right)}\left(\ln \left(N^{\frac{1}{d}}\right)-O(1)\right) .
\end{aligned}
$$

Construction of the Graph $\mathcal{G}_{\alpha, \beta}$. Now we describe in detail how the graph $\mathcal{G}_{\alpha, \beta}$ is constructed. We choose $\alpha$ and the parameters $x, y$ such as to satisfy the following constraints:
(1) $\left|\left[N^{a / d}, N^{b / d}\right]\right| \geq N$.
(2) $|[x \Delta, y \Delta]|=o\left(N^{\frac{d-1}{d}}\right)$, where $N^{\frac{d-1}{d}}$ is a lower bound for the size of an optimum dominating set in $G_{U, \mathcal{S}}$.
(3) $\sum_{j=x \Delta}^{y \Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j=\operatorname{vol}(|x \Delta, y \Delta|) \geq \zeta(\beta) \cdot e^{\alpha}$, i. e. the total volume of the set $[x \Delta, y \Delta]$ is large enough such that $[x \Delta, y \Delta]$ can dominate the wheel $W$ as well as all the degree 2 nodes, which are matched to nodes in the graph $G_{U, \mathcal{S}}$.

Constraint (1) is implied by the following stronger constraint: $e^{\alpha} \cdot N^{-b \beta / d} \geq N$. In all of the following cases, we work with this constraint instead of (1) and obtain the following bound for the parameter $\alpha: e^{\alpha} \geq N^{1+b \beta / d}$. In order to minimize the value of the parameter $\alpha$-and therefore the overall graph size-we choose $e^{\alpha}=N^{1+b \beta / d}$.

### 7.1 The Case $0<\beta<1$

Now we consider the case $0<\beta<1$. Here, we have to make use of our scaling technique. Furthermore, in this case we have to choose parameters $x, y$ of the interval $X=[x \Delta, y \Delta]$ carefully in order to obtain a logarithmic lower bound. The next lemma provides an estimate for the size of the interval $[x \Delta, y \Delta]$ and the volume $\operatorname{vol}([x \Delta, y \Delta])$.

Lemma 2. Let $0<\beta<1$ and $X=[x \Delta, y \Delta]$. We have the following bounds on the size and the volume of the underlying interval:

$$
\begin{aligned}
& |[x \Delta, y \Delta]| \in\left[\frac{\Delta}{1-\beta}\left(1-x^{1-\beta}\right)-\left(\frac{1}{x^{\beta}}-1\right)-(2-x) \Delta, \frac{\Delta}{1-\beta}\left(1-x^{1-\beta}\right)\right] \quad \text { and } \\
& \quad \operatorname{vol}([x \Delta, y \Delta]) \geq \Delta^{2}\left(\frac{1-x^{2-\beta}}{2-\beta}-\frac{1}{2}+\frac{x^{2}}{2}\right)-\Delta\left(1-x^{1-\beta}-\frac{1}{2}+\frac{x}{2}\right)
\end{aligned}
$$

Proof. Regarding the requirement of constraint (2) of the construction, we have

$$
|[x \Delta, y \Delta]| \in\left[\sum_{j=x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta}}-(y-x+1) \Delta, \sum_{j=x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta}}\right],
$$

where

$$
\begin{aligned}
\sum_{j=x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta}} & \in\left[e^{\alpha} \int_{x \Delta}^{y \Delta} \frac{1}{j^{\beta}} \mathrm{d} j-e^{\alpha}\left(\frac{1}{(x \Delta)^{\beta}}-\frac{1}{(y \Delta)^{\beta}}\right), e^{\alpha} \int_{x \Delta}^{y \Delta} \frac{1}{j^{\beta}} \mathrm{d} j\right] \\
& =\left[e^{\alpha}\left[\frac{j^{1-\beta}}{1-\beta}\right]_{x \Delta}^{y \Delta}-\frac{e^{\alpha}}{\Delta^{\beta}}\left(\frac{1}{x^{\beta}}-\frac{1}{y^{\beta}}\right), e^{\alpha}\left[\frac{j^{1-\beta}}{1-\beta}\right]_{x \Delta}^{y \Delta}\right] \\
& =\left[\frac{e^{\alpha} \Delta^{1-\beta}}{1-\beta}\left(y^{1-\beta}-x^{1-\beta}\right)-\left(\frac{1}{x^{\beta}}-\frac{1}{y^{\beta}}\right), \frac{e^{\alpha} \Delta^{1-\beta}}{1-\beta}\left(y^{1-\beta}-x^{1-\beta}\right)\right] \\
& =\left[\frac{\Delta}{1-\beta}\left(y^{1-\beta}-x^{1-\beta}\right)-\left(\frac{1}{x^{\beta}}-\frac{1}{y^{\beta}}\right), \frac{\Delta}{1-\beta}\left(y^{1-\beta}-x^{1-\beta}\right)\right]
\end{aligned}
$$

In order to fulfill the volume requirement of constraint (3), we have to take into account the rounding error resulting when we replace the sum $\sum_{x \Delta}^{y \Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta-1}}\right\rfloor$ by $\sum_{x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta-1}}$. The sum of node degrees of nodes in $[x \Delta, y \Delta]$ is

$$
\operatorname{vol}([x \Delta, y \Delta])=\sum_{x \Delta}^{y \Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j \in[\sum_{x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta-1}}-\underbrace{\left(\frac{y \Delta(y \Delta-1)}{2}-\frac{x \Delta(x \Delta-1)}{2}\right)}_{\text {rounding error }}, \sum_{x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta-1}}],
$$

where

$$
\begin{aligned}
\sum_{x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta-1}} & \in\left[e^{\alpha} \int_{x \Delta}^{y \Delta} j^{1-\beta} \mathrm{d} j-e^{\alpha}\left((y \Delta)^{1-\beta}-(x \Delta)^{1-\beta}\right), e^{\alpha} \int_{x \Delta}^{y \Delta} j^{1-\beta} \mathrm{d} j\right] \\
& =\left[e^{\alpha}\left[\frac{j^{2-\beta}}{2-\beta}\right]_{x \Delta}^{y \Delta}-\Delta\left(y^{1-\beta}-x^{1-\beta}\right), e^{\alpha}\left[\frac{j^{2-\beta}}{2-\beta}\right]_{x \Delta}^{y \Delta}\right] \\
& =\left[\frac{\Delta^{2}}{2-\beta}\left(y^{2-\beta}-x^{2-\beta}\right)-\Delta\left(y^{1-\beta}-x^{1-\beta}\right), \frac{\Delta^{2}}{2-\beta}\left(y^{2-\beta}-x^{2-\beta}\right)\right] .
\end{aligned}
$$

We choose $y=1$ and obtain

$$
|[x \Delta, \Delta]| \in\left[\frac{\Delta}{1-\beta}\left(1-x^{1-\beta}\right)-\left(\frac{1}{x^{\beta}}-1\right)-(2-x) \Delta, \frac{\Delta}{1-\beta}\left(1-x^{1-\beta}\right)\right] .
$$

The volume of that interval is then estimated as

$$
\begin{align*}
\operatorname{vol}([x \Delta, \Delta]) & \geq \frac{\Delta^{2}}{2-\beta}\left(1-x^{2-\beta}\right)-\Delta\left(1-x^{1-\beta}\right)-\left(\frac{\Delta(\Delta+1)}{2}-\frac{x^{2} \Delta^{2}-x \Delta}{2}\right) \\
& =\frac{\Delta^{2}}{2-\beta}\left(1-x^{2-\beta}\right)-\frac{\Delta^{2}}{2}+\frac{x^{2}}{2} \Delta^{2}-\Delta\left(1-x^{1-\beta}-\frac{1}{2}+\frac{x}{2}\right) \\
& =\Delta^{2}\left(\frac{1-x^{2-\beta}}{2-\beta}-\frac{1}{2}+\frac{x^{2}}{2}\right)-\Delta\left(1-x^{1-\beta}-\frac{1}{2}+\frac{x}{2}\right) \tag{7.1}
\end{align*}
$$

which finishes the proof.
Now we use the scaling technique with scaling parameter $d$. Thus we have to choose $\alpha$ such that $e^{\alpha} \geq N^{\frac{d+b \beta}{d}}$. Since $N^{\frac{d-1}{d}}$ is a lower bound for the optimum in $G_{U, \mathcal{S}}^{d}$, we have $N^{\frac{d-1}{d}}=e^{\frac{d-1}{d+b \beta} \cdot \alpha}=$ $e^{(1-\delta) \alpha}$, where we can choose $1-\delta$ arbitrary close to 1 . The size of the interval $[x \Delta, \Delta]$ is of order $\Delta\left(1-x^{1-\beta}\right)$, hence we want to choose $x$ such that $\Delta\left(1-x^{1-\beta}\right)=e^{\alpha / \beta} \cdot e^{p}$ with $\alpha / \beta \cdot p<(1-\delta) \alpha$, i.e. $p<(1-\delta) \beta$. So suppose we choose $x$ such that $p=\left(1-\delta^{\prime}\right) \beta$, where $1-\delta^{\prime}$ can be chosen arbitrary close to 1. Furthermore, the interval $[x \Delta, \Delta]$ needs to provide sufficient volume to dominate the rest of the graph, i.e. (using Lemma 2) we require that $\Delta^{2}\left(\frac{1}{2-\beta}-\frac{1}{2}-x^{2-\beta}\left(\frac{1}{2-\beta}-\frac{x^{\beta}}{2}\right)\right)>\Delta$. This yields the requirement $\frac{1}{2-\beta}-\frac{1}{2}-x^{2-\beta}\left(\frac{1}{2-\beta}-\frac{x^{\beta}}{2}\right)>\frac{1}{\Delta}$, which is implied by $1-\frac{1}{\Delta\left(\frac{1}{2-\beta}-\frac{1}{2}\right)}>x^{2}$. Combining this with the upper bound requirement for the size of the interval, we obtain

$$
\begin{equation*}
\left(1-\frac{1-\beta}{e^{\alpha\left(\frac{1}{\beta}-\left(1-\delta^{\prime}\right)\right)}}\right)^{\frac{1}{1-\beta}} \leq x<\left(1-\frac{1}{\left(\frac{1}{2-\beta}-\frac{1}{2}\right) \cdot e^{\frac{\alpha}{\beta}}}\right)^{\frac{1}{2}} \tag{7.2}
\end{equation*}
$$

We observe that $\frac{1}{1-\beta}>1>\frac{1}{2}$ for $\beta \in(0,1)$, and furthermore $\frac{\alpha}{\beta}-\left(1-\delta^{\prime}\right) \alpha<\frac{\alpha}{\beta}$. Hence we can choose $x$ such that Equation 7.2 holds. Thus for this choice of $x$ we have $|[x \Delta, \Delta]|=o\left(N^{\frac{d-1}{d}}\right)$ and $\operatorname{vol}([x \Delta, \Delta]) \geq\left|\mathcal{G}_{\alpha, \beta}\right|$, fulfilling the constraints (2) and (3) of the graph $\mathcal{G}_{\alpha, \beta}$. We have $\operatorname{OPT}\left(\mathcal{G}_{\alpha, \beta}\right)=(1+o(1)) \operatorname{OPT}\left(G_{U, \mathcal{S}}^{d}\right)$, and furthermore $N=\left(\left|\mathcal{G}_{\alpha, \beta}\right| \cdot(1-\beta)\right)^{\frac{d \beta}{d+b \beta}}$. Altogether we obtain the following result.

Theorem 1. For $0<\beta<1$, the Min-DS problem on $(\alpha, \beta)$-PLGs is hard to approximate within

$$
\frac{(1-\varepsilon) \varepsilon}{2+\varepsilon} \cdot\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} \cdot\left(\frac{\beta}{d+b \beta} \cdot\left(\ln \left(\left|\mathcal{G}_{\alpha, \beta}\right|\right)-\ln \left(\frac{1}{1-\beta}\right)\right)-O(1)\right)
$$

### 7.2 The Case $\beta=1$

In the case $\beta=1$, we can omit the scaling and directly embed the graph $G_{U, \mathcal{S}}$ into a PLG $\mathcal{G}_{\alpha, \beta}$. It suffices to describe the choice of parameters $x$ and $\alpha$ for a given $G_{U, \mathcal{S}}$ and to verify that the constraints (1)-(3) of the graph $\mathcal{G}_{\alpha, \beta}$ are satisfied. It turns out that if we choose $x$ such that $\ln (1 / x)=o\left(e^{\alpha \cdot \frac{b}{1+b}}\right)$ and $N_{0}^{1+b}=e^{\alpha}$, we obtain the following lower bound.

Theorem 2. For $\beta=1$, the Min-DS problem on $(\alpha, \beta)$-PLGs is hard to approximate within

$$
\frac{(1-\varepsilon) \varepsilon}{2+\varepsilon} \cdot\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} \cdot\left(\frac{(1-o(1)) \ln \left(\left|\mathcal{G}_{\alpha, \beta}\right|\right)}{1+b}-O(1)\right) .
$$

In order to prove the theorem, we have to describe the choice of parameters $x$ and $\alpha$ for a given $G_{U, \mathcal{S}}$ such as to satisfy the constraints (1)-(3). We make use of the following lemma.

Lemma 3. Let $\beta=1$ and $X=[x \Delta, y \Delta]$. We have the following bounds on the size and the volume of the interval:

$$
\begin{gathered}
|[x \Delta, y \Delta]| \in\left[e^{\alpha} \ln \left(\frac{1}{x}\right)-\left(\frac{1}{x}-1\right), e^{\alpha} \ln \left(\frac{1}{x}\right)\right] \text { and } \\
\operatorname{vol}([x \Delta, y \Delta]) \in\left[\Delta^{2}\left(\frac{1}{2}-x+\frac{x^{2}}{2}\right)-\frac{1-x}{2} \Delta,(1-x) \Delta^{2}\right] .
\end{gathered}
$$

Proof. For a given $x \in[0,1]$, the size of the interval $[x \Delta, \Delta]=\left\{v \in V\left(\mathcal{G}_{\alpha, \beta}\right) \mid x \Delta \leq \operatorname{deg}_{\alpha, \beta}(v) \leq \Delta\right\}$ satisfies

$$
\begin{aligned}
|[x \Delta, \Delta]| & \in\left[\sum_{x e^{\alpha}}^{e^{\alpha}} \frac{e^{\alpha}}{j}-(1-x) e^{\alpha}, \sum_{x e^{\alpha}}^{e^{\alpha}} \frac{e^{\alpha}}{j}\right] \\
& \subseteq\left[e^{\alpha}\left(\ln \left(e^{\alpha}\right)-\ln \left(x e^{\alpha}\right)\right)-e^{\alpha}\left(\frac{1}{x}-1\right) \cdot \frac{1}{e^{\alpha}}, e^{\alpha} \cdot \ln \left(\frac{1}{x}\right)\right] \\
& =\left[e^{\alpha} \ln \left(\frac{1}{x}\right)-\left(\frac{1}{x}-1\right), e^{\alpha} \ln \left(\frac{1}{x}\right)\right] .
\end{aligned}
$$

The volume of that interval is

$$
\begin{aligned}
\operatorname{vol}([x \Delta, \Delta]) & \in\left[\sum_{x \Delta}^{\Delta} e^{\alpha}-j, \sum_{x \Delta}^{\Delta} e^{\alpha}\right] \\
& \subseteq\left[e^{\alpha}(1-x) \Delta-\left(\frac{\Delta(\Delta+1)}{2}-\frac{x \Delta(x \Delta+1)}{2}\right), e^{\alpha}(1-x) \Delta\right] \\
& =\left[\Delta^{2}\left(\frac{1}{2}-x+\frac{x^{2}}{2}\right)-\frac{1-x}{2} \Delta,(1-x) \Delta^{2}\right] .
\end{aligned}
$$

Proof of Theorem 2. From Lemma 3, we obtain that for every $x<1$ being bounded away from 1, the volume of the interval $[x \Delta, \Delta]$ is $\omega\left(\left|G_{\alpha, 1}\right|\right)$. Recall that in order to achieve $N_{0} \leq\left|\left[N_{0}^{a}, N_{0}^{b}\right]\right|$, it suffices to choose $\alpha$ sufficiently large such that $N_{0} \leq \frac{e^{\alpha}}{N_{0}^{b /}}=\frac{e^{\alpha}}{N_{0}^{b}}$. Hence suppose we have $N_{0}^{1+b}=e^{\alpha}$. This implies $\frac{e^{\alpha}}{N_{0}^{b}}=e^{\alpha \cdot \frac{1}{1+b}}$. Thus it suffices to choose $x$ such that $\ln \left(\frac{1}{x}\right)=o\left(e^{\alpha \cdot \frac{b}{1+b}}\right)$. The size of the PLG is $\left|\mathcal{G}_{\alpha, \beta}\right|=\alpha e^{\alpha}$, and from $N_{0}^{1+b}=e^{\alpha}$ we obtain $N_{0}=e^{\frac{\alpha}{1+b}}=\left(\frac{\left|\mathcal{G}_{\alpha, \beta}\right|}{\ln \left(\mathcal{G}_{\alpha, \beta}\right)}\right)^{\frac{1}{1+b}}$. Hence, we
obtain the same lower bound as for the case $0<\beta<1$ stated in Theorem 1 . This concludes the proof of Theorem 2.

### 7.3 The Case $1<\beta \leq 2$

In this section we consider the case $1<\beta \leq 2$. We start with the subcase $1<\beta<2$. The following lemma provides estimates for the sizes and volumes of node intervals of the form $[x \Delta, y \Delta]$.

Lemma 4. Let $1<\beta<2$ and $X=[x \Delta, y \Delta]$. We have the following bounds on the size and the volume of the interval:

$$
|[x \Delta, y \Delta]| \in\left[\Delta(y-x)\left(\frac{1}{y^{\beta}}-1\right), \Delta \frac{y-x}{x^{\beta}}\right]
$$

and

$$
\operatorname{vol}([x \Delta, \Delta]) \geq(1-o(1)) \Delta^{2} \cdot \frac{\beta-2 x^{2-\beta}+(2-\beta) x^{2}}{2 \cdot(2-\beta)}
$$

Proof. For $1<\beta<2$, we have the following estimate for the size of the node interval $[x \Delta, y \Delta]$ :

$$
\begin{aligned}
|[x \Delta, y \Delta]| & \in\left[\frac{e^{\alpha}}{\Delta^{\beta}}(y-x) \Delta \frac{1}{y^{\beta}}-(y-x) \Delta, \frac{e^{\alpha}}{\Delta^{\beta}}(y-x) \Delta \frac{1}{x^{\beta}}\right] \\
& =\left[\Delta(y-x)\left(\frac{1}{y^{\beta}}-1\right), \Delta \frac{y-x}{x^{\beta}}\right]
\end{aligned}
$$

The volume $\operatorname{vol}(|x \Delta, y \Delta|)=\sum_{j=x \Delta}^{y \Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j$ can be estimated as follows:

$$
\begin{aligned}
\operatorname{vol}(|x \Delta, y \Delta|) & \geq e^{\alpha} \sum_{j=x \Delta}^{y \Delta} j^{1-\beta}-r_{\beta} \\
& =(1-o(1)) e^{\alpha} \cdot \int_{x \Delta}^{y \Delta} j^{1-\beta} \mathrm{d} j-r_{\beta} \\
& =(1-o(1)) e^{\alpha} \cdot\left[\frac{j^{2-\beta}}{2-\beta}\right]_{x \Delta}^{y \Delta}-r_{\beta} \\
& =(1-o(1)) e^{\alpha} \cdot e^{\alpha \frac{2-\beta}{\beta}} \cdot \frac{y^{2-\beta}-x^{2-\beta}}{2-\beta}-r_{\beta} \\
& =(1-o(1)) \Delta^{2} \cdot \frac{y^{2-\beta}-x^{2-\beta}}{2-\beta}-r_{\beta}
\end{aligned}
$$

where $r_{\beta}=\frac{\Delta^{2}\left(y^{2}-x^{2}\right)}{2}+\frac{\Delta(y+x)}{2}$ is an upper bound for the rounding error. We conclude that $\operatorname{vol}([x \Delta, y \Delta])=\omega\left(\left|\mathcal{G}_{\alpha, \beta}\right|\right)$, provided we choose $x$ and $y$ in such a way that $\frac{y^{2-\beta}-x^{2-\beta}}{2-\beta}-r_{\beta}>0$. Let
us choose $y=1$. Then, we have

$$
\frac{y^{2-\beta}-x^{2-\beta}}{2-\beta}-r_{\beta}=\frac{1-x^{2-\beta}}{2-\beta}-\frac{1-x^{2}}{2}-o(1)=\frac{\beta-2 x^{2-\beta}+(2-\beta) x^{2}}{2 \cdot(2-\beta)}-o(1) .
$$

Now, we want to choose $x \in(0,1)$ such that $\beta-2 x^{2-\beta}+(2-\beta) x^{2}>0$. This inequality holds for $x<(\beta / 2)^{\frac{1}{2-\beta}}$, since $\frac{\beta}{2}<1$. For our choice of $\alpha$, we have that $N^{\frac{d-1}{d}}=e^{\alpha \cdot \frac{d-1}{d+b \beta}}$, and hence constraint (2) holds if the following constraint is satisfied: $\Delta \cdot \frac{y-x}{x^{\beta}}=\frac{y-x}{x^{\beta}} \cdot e^{\frac{\alpha}{\beta}}=o\left(e^{\alpha \cdot \frac{d-1}{d+b \beta \beta}}\right)$. Hence, for our choice of $y=1$ and $x<(\beta / 2)^{\frac{1}{2-\beta}}$, this last constraint is satisfied if $\frac{\alpha}{\beta}<\alpha \cdot \frac{d-1}{d+b \beta}$, i. e. when $d>\frac{(b+1) \beta}{\beta-1}$.

We proceed similarly in the case $\beta=2$ and obtain a slightly different version of Lemma 4.
Lemma 5. Let $\beta=2$ and $X=[x \Delta, y \Delta]$. We have the following bounds on the size and the volume of the interval:

$$
|[x \Delta, y \Delta]| \in\left[\sqrt{e^{\alpha}} \cdot \frac{y-x}{y^{\beta}}, \sqrt{e^{\alpha}} \cdot \frac{y-x}{x^{\beta}}\right] \quad \text { and } \quad \operatorname{vol}([x \Delta, y \Delta])=(1-o(1)) e^{\alpha} \ln \left(\frac{1}{x}\right) .
$$

Proof. We give an estimate of the size of the interval $[x \Delta, y \Delta]$ and of the volume of that interval. We have that

$$
|[x \Delta, y \Delta]| \in\left[\Delta \frac{y-x}{y^{\beta}}, \Delta \frac{y-x}{x^{\beta}}\right]=\left[\sqrt{e^{\alpha}} \cdot \frac{y-x}{y^{\beta}}, \sqrt{e^{\alpha}} \cdot \frac{y-x}{x^{\beta}}\right] .
$$

The value $\operatorname{vol}([x \Delta, y \Delta])$ of the interval is $(1-o(1)) \sum_{j=x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta}} j=(1-o(1)) e^{\alpha}(\ln (y \Delta)-\ln (x \Delta))$ $=(1-o(1)) e^{\alpha}\left(\ln \left(\frac{1}{x}\right)-\ln \left(\frac{1}{y}\right)\right)$. We choose $y=1$ and obtain

$$
\operatorname{vol}([x \Delta, y \Delta])=(1-o(1)) \sum_{j=x \Delta}^{y \Delta} \frac{e^{\alpha}}{j^{\beta}} \cdot j=(1-o(1)) e^{\alpha}\left(\ln \left(\frac{1}{x}\right)-0\right) .
$$

Hence, we choose $x$ such that $\ln \left(\frac{1}{x}\right) \geq \zeta(\beta)$, i.e. $x \leq \frac{1}{e^{\zeta(\beta)}}$. Then the volume of the interval $[x \Delta, \Delta]$ suffices to dominate the rest of the graph and constraint (3) is satisfied. The size of the interval $[x \Delta, \Delta]$ satisfies $|[x \Delta, \Delta]| \in\left[\Delta \frac{1-x}{1}, \Delta \frac{1-x}{x^{\beta}}\right]$. The two intervals $[x \Delta, \Delta]$ and $\left[N^{a / d}, N^{b / d}\right]$ need to be node disjoint. Hence, we want to choose $d$ such that $N^{b / d}<x \Delta$. For $x=\frac{1}{e^{\zeta(\beta)}}$, we have $x \Delta=e^{\alpha / \beta-\zeta(\beta)}$. Furthermore, the size $N$ of the graph $G_{U, \mathcal{S}}^{d}$ satisfies $N=\left|G_{U, \mathcal{S}}^{d}\right| \leq e^{\alpha \frac{d}{d+b \beta}}$. This yields the following bound for the scaling parameter $d$ : $N^{b / d}<x \Delta \Longleftrightarrow e^{\alpha b \cdot \frac{1}{d+b \beta}}<e^{\alpha / \beta-\zeta(\beta)} \Longleftrightarrow$ $d>\frac{\alpha \cdot b}{\alpha / \beta-\zeta(\beta)}-b \beta$.

Resulting Lower Bound. Since the parameter $\alpha$ is chosen such that $e^{\alpha}=N^{1+\frac{b \beta}{d}}$, we have $\left|\mathcal{G}_{\alpha, \beta}\right|=\zeta(\beta) \cdot N^{1+\frac{b \beta}{d}}$. Thus we obtain the following bounds on the size of an optimum dominating set for $\mathcal{G}_{\alpha, \beta}:$ If $\frac{\left|\mathcal{G}_{\alpha, \beta}\right|}{\zeta(\beta)}=\phi$, then

$$
\begin{aligned}
& \left|\mathrm{OPT}\left(\mathcal{G}_{\alpha, \beta}\right)\right| \leq\left(\phi^{\frac{d}{d+b \beta}}\right)^{\frac{d-1}{d}} k\left(\phi^{\frac{d}{d+b \beta}}\right)^{\frac{1}{d} \frac{\varepsilon}{2+\varepsilon}}=k\left(\phi^{\frac{d-1+\frac{\varepsilon}{d+b,}}{d+b \beta}}\right) \text { or } \\
& \left|\operatorname{OPT}\left(\mathcal{G}_{\alpha, \beta}\right)\right| \geq k\left(\phi^{\frac{d-1+\frac{\varepsilon}{2+\varepsilon}}{d+b \beta}}\right) \frac{(1-\varepsilon) \varepsilon}{2+\varepsilon}\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}}\left(\ln \left(\phi^{\frac{d}{d+b \beta} \frac{1}{d}}\right)-O(1)\right) .
\end{aligned}
$$

Altogether, we obtain the following theorem.
Theorem 3. For $1<\beta \leq 2$, the Min-DS problem on ( $\alpha, \beta$ )-power law graphs is hard to approximate within

$$
\frac{(1-\varepsilon) \cdot \varepsilon}{2+\varepsilon} \cdot\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} \cdot \frac{\ln \left(\left|\mathcal{G}_{\alpha, \beta}\right|\right)-\ln (\zeta(\beta))}{d+b \beta}
$$

## 8 New Upper Bounds for $\beta>2$

Now we are going to prove new upper bounds for Min-DS for $\beta>2$. It was already observed by Shen et al. [21] that, in the case of $\beta>2$, the Min-DS problem on $(\alpha, \beta)$-PLG is in the class APX. They showed that there exists an efficient approximation algorithm with approximation ratio $(\zeta(\beta)-1 / 2) /\left(\zeta(\beta)-\sum_{j=1}^{t_{0}} 1 / j^{\beta}\right)$ for some $t_{0}=O(1)$. In this section we give a new and explicit upper bound, based on our techniques of estimating sizes and volumes of intervals in $(\alpha, \beta)$-PLG. The lower bound on the size of a dominating set in $\mathcal{G}_{\alpha, \beta}$ given in part (ii) of the following lemma was also used in [21].

## Lemma 6.

(i) If $\operatorname{vol}([x \Delta, \Delta])=\sum_{j=x \Delta}^{\Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j<\left\lfloor e^{\alpha}\right\rfloor$, then $|[x \Delta, \Delta]|$ is a lower bound on the size of $a$ dominating set in $\mathcal{G}_{\alpha, \beta}$.
(ii) If $\operatorname{vol}([x \Delta, \Delta])=\sum_{j=x \Delta}^{\Delta}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor \cdot j<\sum_{j=1}^{x \Delta-1}\left\lfloor\frac{e^{\alpha}}{j^{\beta}}\right\rfloor$, then $|[x \Delta, \Delta]|$ is a lower bound on the size of a dominating set in $\mathcal{G}_{\alpha, \beta}$.

Proof. Considering (i), let $D$ be a dominating set in $\mathcal{G}_{\alpha, \beta}$, and let $D_{1}=D \cap[x \Delta, \Delta]$ and $D_{2}=D \backslash$ $D_{1}$. Suppose $\left|D_{2}\right|<\left|[x \Delta, \Delta] \backslash D_{1}\right|$. Since $\forall v \in D_{2}, u \in[x \Delta, \Delta] \backslash D_{1}$ we have $\operatorname{deg}_{\alpha, \beta}(v)<\operatorname{deg}_{\alpha, \beta}(u)$, this implies $\operatorname{vol}\left(D_{2}\right)<\operatorname{vol}\left([x \Delta, \Delta] \backslash D_{1}\right)$ and thus $\operatorname{vol}(D)<\operatorname{vol}([x \Delta, \Delta])<\left\lfloor e^{\alpha}\right\rfloor$, a contradiction.

Suppose in case (ii) that $\operatorname{vol}([x \Delta, \Delta])<|[1, x \Delta-1]|$ and that $D, D_{1}, D_{2}$ are the same as in the proof of (i). Again we obtain $\operatorname{vol}\left(D_{2}\right)<\operatorname{vol}\left([x \Delta, \Delta] \backslash D_{1}\right)$, which implies $\operatorname{vol}(D)<\operatorname{vol}([x \Delta, \Delta])<$ $\mid[1, x \Delta-1]$. Thus the volume of $D$ is not sufficient to dominate the subset $[1, x \Delta-1]$, a contradiction.

We will now analyze upper bounds for the approximability of Min-DS based on the lower bounds from Lemma 6. Instead of just giving upper and lower bounds on the size of an optimum dominating set and a greedy solution separately, we will explicitly relate upper and lower bound to each other. Let $\mathcal{G}_{\alpha, \beta}$ be an $(\alpha, \beta)$-PLG with $\beta>2$. Let $W$ be the set of neighbors of degree 1 nodes of degree at least 2 in $\mathcal{G}_{\alpha, \beta}$ and let $M$ be the set of degree 1 nodes in $\mathcal{G}_{\alpha, \beta}$ which are adjacent to another degree 1 node. Let $R=V \backslash\left(W \cup\left\{v \in V \mid \operatorname{deg}_{\alpha, \beta}(v)=1\right\}\right)$. Then there exists some $c=c_{\beta}>0$ not depending on $\alpha$ such that $|W| \geq c \cdot e^{\alpha}$. This implies $|R| \leq(\zeta(\beta)-c-1) e^{\alpha}$.

Lemma 7. If $\mathcal{G}_{\alpha, \beta}$ is a connected $(\alpha, \beta)$-PLG with $\beta>2$ and $W$ and $R$ are defined as above, then there exists an optimum dominating set OPT in $\mathcal{G}_{\alpha, \beta}$ with $O P T=O P T_{R} \cup W \cup M^{\prime}$, where $O P T_{R}$ is an optimum dominating set for the induced subgraph $\mathcal{G}_{\alpha, \beta}[R]$ on $R$ and $M^{\prime} \subset M$ is of cardinality $\left|M^{\prime}\right|=\frac{|M|}{2}$.

The maximum degree in the subgraph $\mathcal{G}_{\alpha, \beta}[R]$ induced by $R$ is at most $\Delta$. We consider the dominating set $D=W \cup D_{G r} \cup M^{\prime}$ where $D_{G r}$ is a dominating set for $\mathcal{G}_{\alpha, \beta}[R]$ constructed by the greedy algorithm and $M^{\prime} \subset M$ is a subset of size $\frac{|M|}{2}$ dominating $M$. Since $R=V \backslash\left(W \cup V_{1}\right)$ and $\left|\mathrm{OPT}_{R}\right| \leq|R|$, the approximation ratio is at most

$$
\max \left\{\begin{array}{l|l}
\frac{r \cdot\left|\mathrm{OPT}_{R}\right|+|W|+\frac{|M|}{2}}{\left|\mathrm{OPT}_{R}\right|+|W|+\frac{|M|}{2}} \left\lvert\, \begin{array}{l}
\left|\mathrm{OPT}_{R}\right| \leq|R|, \\
r=\min \left\{\frac{\alpha}{\beta}, \frac{|R|}{\left|\mathrm{OPT}_{R}\right|}\right\}
\end{array}\right.
\end{array}\right\} .
$$

Case 1: $\left(r=\frac{\alpha}{\beta}\right)$ This means that $\frac{\alpha}{\beta} \leq \frac{|R|}{\left|\mathrm{OPT}_{R}\right|}$, i.e. $\left|\mathrm{OPT}_{R}\right| \leq \frac{\beta}{\alpha} \cdot|R|$. The upper bound for the approximation ratio is monotone increasing in $\left|\mathrm{OPT}_{R}\right|$, hence it is bounded by

$$
\frac{\frac{\alpha}{\beta} \cdot \frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}}=\frac{|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}} .
$$

Case 2: $\left(r=\frac{|R|}{\left|O P T_{R}\right|}<\frac{\alpha}{\beta}\right) \quad$ Here, we have $\left|\mathrm{OPT}_{R}\right|>\frac{\beta \cdot|R|}{\alpha}$ and obtain

$$
\frac{r \cdot\left|\mathrm{OPT}_{R}\right|+|W|+\frac{|M|}{2}}{\left|\mathrm{OPT}_{R}\right|+|W|+\frac{|M|}{2}}=\frac{|R|+|W|+\frac{|M|}{2}}{\left|\mathrm{OPT}_{R}\right|+|W|+\frac{|M|}{2}} \leq \frac{|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}} .
$$

Now we need to construct an upper bound for the term $\frac{|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}}$. We consider two cases.
Case I: $(\zeta(\beta-1)-1<1)$ In this case, the volume of nodes of degree at least 2 does not suffice to dominate all the degree 1 nodes. Hence in this case, $M \neq \emptyset$. We obtain the following lower bound for the cardinality of $M:|M| \geq e^{\alpha}-(\zeta(\beta-1)-1) e^{\alpha}=(2-\zeta(\beta-1)) e^{\alpha}$. Nevertheless we will use the upper bound $|R| \leq(\zeta(\beta)-1) e^{\alpha}$. Since the term $\frac{|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}}$ is monotone increasing
in $|R|$, we obtain

$$
\rho(\beta)=\frac{|R|+|W|+\frac{|M|}{2}}{\frac{\beta}{\alpha} \cdot|R|+|W|+\frac{|M|}{2}} \leq \frac{(\zeta(\beta)-1) e^{\alpha}+\frac{(2-\zeta(\beta-1)) e^{\alpha}}{2}}{\frac{\beta}{\alpha}(\zeta(\beta)-1) e^{\alpha}+\frac{(2-\zeta(\beta-1)) e^{\alpha}}{2}}=\frac{\zeta(\beta)-\frac{\zeta(\beta-1)}{2}}{1-\frac{\zeta(\beta-1)}{2}}=\frac{\zeta(\beta-1)-2 \zeta(\beta)}{\zeta(\beta-1)-2} .
$$

Case II: $(\zeta(\beta-1)-1 \geq 1) \quad$ In this case, the volume of the nodes of degree at least 2 suffices to dominate the degree 1 nodes. Now, we construct a lower bound for $|W|$ as follows:

$$
\begin{aligned}
|W| & \geq \min \left\{|[d, \Delta]| \mid \operatorname{vol}([d, \Delta])>e^{\alpha}\right\} \\
& =\min \left\{\left(\zeta(\beta)-\sum_{j=1}^{d-1} \frac{1}{j^{\beta}}\right) e^{\alpha} \left\lvert\,\left(\zeta(\beta-1)-\sum_{j=1}^{d-1} \frac{1}{j^{\beta-1}}\right) e^{\alpha}>e^{\alpha}\right.\right\} .
\end{aligned}
$$

Hence, in this case, the approximation ratio is bounded by

$$
\rho^{\prime}(\beta)=\frac{\zeta(\beta)-1}{\frac{\beta}{\alpha} \cdot|[1, d-1]|+|[d, \Delta]|}=\frac{\zeta(\beta)-1}{\zeta(\beta)-\sum_{j=1}^{d-1} \frac{1}{j^{\beta}}},
$$

where $d=\min \left\{d^{\prime} \mid \operatorname{vol}\left(\left[d^{\prime}, \Delta\right]\right)>e^{\alpha}\right\}$.
Altogether, we obtain the following theorem.
Theorem 4. For $2<\beta \leq 2.729$, the Min-DS problem on $(\alpha, \beta)$-power law graph is approximable within approximation ratio $\rho^{\prime}(\beta)$ and for $\beta>2.729$ within approximation ratio $\rho(\beta)$, where $d=$ $\min \left\{d^{\prime} \mid \operatorname{vol}\left(\left[d^{\prime}, \Delta\right]\right)>e^{\alpha}\right\}$ and

$$
\rho^{\prime}(\beta)=\frac{\zeta(\beta)-1}{\zeta(\beta)-\sum_{j=1}^{d-1} \frac{1}{j^{\beta}}} \quad \text { and } \quad \rho(\beta)=\frac{\zeta(\beta)-\frac{\zeta(\beta-1)}{2}}{1-\frac{\zeta(\beta-1)}{2}} .
$$

In Figure 4 we present a plot of the above approximation ratios $\rho(\beta)$ and $\rho^{\prime}(\beta)$ in the valid ranges for certain choices of the parameter $d$.
In what follows, we are going to analyze the functional dependencies of a parameter $\beta$.

## 9 The Functional Case $\beta_{f}=2+f(n)^{-1}$

We consider the case when the parameter $\beta$ is a function of the size $n$ of the power law graph, converging to 2 from above. This can be seen as a combinatorial variant of preferential attachment PLG. In the preceding sections we have shown that for $\beta \leq 2$, there is a logarithmic lower bound for the approximability of the Min-DS problem in $(\alpha, \beta)$-PLG. On the other hand, for $\beta>2$ the problem is in APX (cf. Shen et al. [21] and the previous section). Thus we will now have a closer look at this phase transition at $\beta=2$. Similar as in our previous paper (cf. [11]), we consider the case when $\beta$ is a function of the size $n$ of the power law graph such that this function converges

Figure 4: Plot of the approximation ratios $\rho(\beta)$ and $\rho^{\prime}(\beta)$ (solid line) in the valid ranges for certain choices of the parameter $d=\min \left\{d^{\prime} \mid \operatorname{vol}\left(\left[d^{\prime}, \Delta\right]\right)>e^{\alpha}\right\}$, in comparison to the results of Shen et al. [21] (dashed line)
to 2 from above. Surprisingly we will obtain a very tight phase transition of the computational complexity of the problem, depending on the convergence rate of the function. Let us first give a precise description of the model.

Let $f: \mathbb{N} \rightarrow \mathbb{N}$ be a monotone increasing unbounded function. For $\beta_{f}=2+f(n)^{-1}$, an $\left(\alpha, \beta_{f}\right)$ PLG is an undirected multigraph $\mathcal{G}_{\alpha, \beta_{f}}$ with $n$ nodes and maximum degree $\Delta_{f}=\left\lfloor e^{\alpha / \beta_{f}}\right\rfloor$ such that for $j=1, \ldots, \Delta_{f}=\left\lfloor e^{\alpha / \beta_{f}}\right\rfloor$, the number of nodes of degree $j$ in $\mathcal{G}_{\alpha, \beta_{f}}$ equals $\left\lfloor\frac{e^{\alpha}}{j^{\beta_{f}}}\right\rfloor$. Especially this means that $\sum_{j=1}^{\Delta_{f}}\left\lfloor\frac{e^{\alpha}}{j^{2+1 / f(n)}}\right\rfloor=n$.

We consider two cases for $\beta_{f}=2+f(n)^{-1}$, namely, $f(n)=\omega(\log (n)$ and $f(n)=o(\log (n))$. For the case $f(n)=\omega(\log (n))$, we obtain the following theorem.

Theorem 5. For $\beta_{f}=2+f(n)^{-1}$ with $f(n)=\omega(\log (n))$, the Min-DS problem on $\left(\alpha, \beta_{f}\right)-P L G$ is hard to approximate within

$$
\frac{(1-\varepsilon) \cdot \varepsilon}{2+\varepsilon} \cdot\left(\frac{1}{2}\right)^{\frac{\varepsilon}{2+\varepsilon}} \cdot \frac{\ln \left(\left|\mathcal{G}_{\alpha, \beta}\right|\right)-\ln (\zeta(\beta))}{d+b \beta} .
$$

Before giving the proof of the theorem, we will first show that the terms $j^{-\beta_{f}}$ converge to $j^{-2}$ as $n \rightarrow \infty$. More precisely, we show that $j^{-\beta_{f}} \in\left[\frac{1}{n^{1 / f(n)}} \cdot \frac{1}{j^{2}}, \frac{1}{j^{2}}\right]$. First, we give an additive bound
for the terms $j^{-\beta_{f}}$ as follows: $\frac{1}{j^{\beta} f}=\frac{1}{j^{2+} \frac{1}{f(n)}} \in\left[\frac{1}{j^{2}}-\tau(n), \frac{1}{j^{2}}\right]$, where

$$
\tau(n)=\max \left\{\left.\frac{1}{j^{2}}-\frac{1}{j^{2-\frac{1}{f(n)}}} \right\rvert\, j=1, \ldots, \Delta_{f}\right\}=\max \left\{\left.\frac{j^{\frac{1}{f(n)}}-1}{j^{2+\frac{1}{f(n)}}} \right\rvert\, j=1, \ldots, \Delta_{f}\right\} .
$$

We consider the function $x \mapsto h(x):=\frac{x^{1 / f(n)}-1}{x^{2+1 / f(n)}}=x^{-2}-x^{-2-\frac{1}{f(n)}}$. Its derivative is $\frac{d}{d x} h(x)=$ $\frac{d}{d x} \frac{x^{1 / f(n)}-1}{x^{2+1 / f(n)}}=-2 x^{-3}+\left(2+\frac{1}{f(n)}\right) x^{-3-\frac{1}{f(n)}}$. The condition $h(x)<0$ is equivalent to $1+\frac{1}{2 f(n)}<$ $x^{\frac{1}{f(n)}}$. We observe that the derivative attains its maximum at $x=2$. We have $h^{\prime}(2)<0 \Longleftrightarrow$ $\left(1+\frac{1}{2 f(n)}\right)^{f(n)}<2$. We observe that $\lim _{n \rightarrow \infty}\left(1+\frac{1}{2 f(n)}\right)^{f(n)}=e^{1 / 2}<2$. Thus, we obtain $\tau(n)=\frac{2^{1 / f(n)}-1}{2^{2+1 / f(n)}}$. Now, we give a multiplicative bound as follows: $\frac{1}{j^{\beta_{f}}}=\frac{1}{j^{2}} \cdot j^{2-\beta_{f}}=\frac{1}{j^{2}} \cdot \frac{1}{j^{1 / f(n)}} \in$ $\left[\frac{1}{n^{1 / f(n)}} \cdot \frac{1}{j^{2}}, \frac{1}{j^{2}}\right]$.

Let us now give sufficiently precise estimates of sizes and volumes of the node intervals in the functional case.

Lemma 8. Let $\beta_{f}=2+\frac{1}{f(n)}$ and $X=\left[x \Delta_{f}, y \Delta_{f}\right]$. We have the following bounds on the size and the volume of the interval:

$$
\begin{aligned}
& \quad\left|\left[x \Delta_{f}, y \Delta_{f}\right]\right| \in \\
& \quad\left[e^{\alpha \frac{f(n)+1}{2 f(n)+1}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)-(y-x) \Delta_{f}, e^{\alpha \frac{f(n)+1}{2 f(n)+1}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)+e^{\alpha \frac{1}{2 f(n)+1}} \cdot\left(\frac{1}{x^{2}}-\frac{1}{y^{2}}\right)\right] \text { and } \\
& \operatorname{vol}\left(\left[x \Delta_{f}, y \Delta_{f}\right]\right) \in \\
& \quad\left[\frac{e^{\alpha}(\ln (y)-\ln (x))}{n^{\frac{1}{f(n)}}}-\frac{\left(y^{2}-x^{2}\right) \Delta_{f}^{2}+(x+y) \Delta_{f}}{2}, e^{\alpha}(\ln (y)-\ln (x))+e^{\alpha}\left(\frac{1}{x \Delta_{f}}-\frac{1}{y \Delta_{f}}\right)\right] .
\end{aligned}
$$

Proof. For $\beta=2$, our technique based on integration yields the following estimate of sizes of intervals:

$$
\begin{aligned}
\sum_{j=x \Delta}^{y \Delta} \frac{1}{j^{2}} & \in\left[\int_{x \Delta}^{y \Delta} j^{-2} \mathrm{~d} j, \int_{x \Delta}^{y \Delta} j^{-2} \mathrm{~d} j+\frac{1}{(x \Delta)^{2}}-\frac{1}{(y \Delta)^{2}}\right] \\
& =\left[\frac{1}{x \Delta}-\frac{1}{y \Delta}, \frac{1}{x \Delta}-\frac{1}{y \Delta}+\frac{1}{(x \Delta)^{2}}-\frac{1}{(y \Delta)^{2}}\right] \\
|[x \Delta, y \Delta]| & \in\left[e^{\alpha / 2} \cdot\left(\frac{1}{x}-\frac{1}{y}\right), e^{\alpha / 2} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)+\frac{1}{x^{2}}-\frac{1}{y^{2}}\right] .
\end{aligned}
$$

We combine this with the multiplicative bound and obtain the following estimate of the size of
intervals in the case $\beta_{f}=2+\frac{1}{f(n)}$.

$$
\begin{gathered}
\left|\left[x \Delta_{f}, y \Delta_{f}\right]\right|=\sum_{j=x \Delta_{f}}^{y \Delta_{f}}\left\lfloor\frac{e^{\alpha}}{j^{\beta_{f}}}\right\rfloor \\
\in\left[e^{\alpha \cdot \frac{1+\frac{1}{f(n)}}{2+\frac{1}{f(n)}}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)-(y-x) \Delta_{f}, e^{\alpha \cdot \frac{1+\frac{1}{f(n)}}{2+\frac{1}{f(n)}}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)+e^{\alpha \cdot\left(1-\frac{1}{1+\frac{1}{2 f(n)}}\right)} \cdot\left(\frac{1}{x^{2}}-\frac{1}{y^{2}}\right)\right] \\
\\
=\left[e^{\alpha \cdot \frac{f(n)+1}{2 f(n)+1}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)-(y-x) \Delta_{f}, e^{\alpha \cdot \frac{f(n)+1}{2 f(n)+1}} \cdot\left(\frac{1}{x}-\frac{1}{y}\right)+e^{\alpha \cdot \frac{1}{2 f(n)+1}} \cdot\left(\frac{1}{x^{2}}-\frac{1}{y^{2}}\right)\right]
\end{gathered}
$$

Especially we obtain the following estimate of the size of $\mathcal{G}_{\alpha, \beta_{f}}$ :

$$
\begin{aligned}
\left|\left[1, \Delta_{f}\right]\right| & \in\left[e^{\alpha}-e^{\alpha \frac{f(n)+1}{2 f(n)+1}}-e^{\alpha \frac{f(n)}{2 f(n)+1}}+1, e^{\alpha}-e^{\alpha \frac{f(n)+1}{2 f(n)+1}}+e^{\alpha \frac{1}{2 f(n)+1}} \cdot e^{2 \alpha \frac{f(n)}{2 f(n)+1}}-e^{\alpha \frac{1}{2 f(n)+1}}\right] \\
& =\left[(1-o(1)) e^{\alpha},(2-o(1)) e^{\alpha}\right]
\end{aligned}
$$

This estimate can be refined as follows:

$$
\begin{aligned}
\sum_{j=1}^{\Delta_{f}}\left\lfloor\frac{e^{\alpha}}{j^{\beta_{f}}}\right\rfloor & \in\left[\sum_{j=1}^{\Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}}}-\Delta_{f}, \sum_{j=1}^{\Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}}}\right] \\
& \subseteq\left[\frac{1}{n^{1 / f(n)}} \cdot \sum_{j=1}^{\Delta_{f}} \frac{e^{\alpha}}{j^{2}}-\Delta_{f}, \sum_{j=1}^{\Delta_{f}} \frac{e^{\alpha}}{j^{2}}\right] \subseteq\left[(1-o(1)) \zeta(2) e^{\alpha}, \zeta(2) e^{\alpha}\right]
\end{aligned}
$$

where the last inclusion holds for $f(n)=\omega(\log (\alpha))$. The volume can be estimated as follows:

$$
\begin{aligned}
\operatorname{vol}\left(\left[x \Delta_{f}, y \Delta_{f}\right]\right) & =\sum_{x \Delta_{f}}^{y \Delta_{f}}\left\lfloor\frac{e^{\alpha}}{j^{\beta_{f}}}\right\rfloor \cdot j \\
& \in\left[\sum_{x \Delta_{f}}^{y \Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}-1}}-\left(x \Delta_{f}+\left(x \Delta_{f}+1\right)+\ldots+y \Delta_{f}\right), \sum_{x \Delta_{f}}^{y \Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}-1}}\right] \\
& =\left[\sum_{x \Delta_{f}}^{y \Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}-1}}-\frac{\left(y^{2}-x^{2}\right) \Delta_{f}^{2}+(x+y) \Delta_{f}}{2}, \sum_{x \Delta_{f}}^{y \Delta_{f}} \frac{e^{\alpha}}{j^{\beta_{f}-1}}\right]
\end{aligned}
$$

Since $j^{\beta_{f}-1}=j^{1+\frac{1}{f(n)}}, j=x \Delta_{f}, y \Delta_{f}$, we use Lemma 23 from our previous paper (cf. [11, p. 23]) and obtain that the $\operatorname{volume} \operatorname{vol}\left(\left[x \Delta_{f}, y \Delta_{f}\right]\right)$ is within the interval

$$
\left[\frac{e^{\alpha} \cdot(\ln (y)-\ln (x))}{n^{\frac{1}{f(n)}}}-\frac{\left(y^{2}-x^{2}\right) \Delta_{f}^{2}+(x+y) \Delta_{f}}{2}, e^{\alpha} \cdot(\ln (y)-\ln (x))+e^{\alpha} \cdot\left(\frac{1}{x \Delta_{f}}-\frac{1}{y \Delta_{f}}\right)\right]
$$

We are now prepared to give the proof of Theorem 5.
Proof of Theorem 5. We compute the parameters $\alpha, d, x, y$ of our embedding $G_{U, \mathcal{S}} \mapsto \mathcal{G}_{\alpha, \beta_{f}}$ for the functional case $\beta_{f}=2+\frac{1}{f(n)}, f(n)=\omega(\log (n))$. In order to satisfy constraint (1), we have to give an estimate for $\left|\left[N^{a / d}, N^{b / d}\right]\right|$. Note that $e^{\alpha \cdot \frac{1}{2 f(n)-1}} \cdot \Delta_{f}^{2}=e^{\alpha \cdot \frac{f(n)+1}{2 f(n)+1}} \cdot \Delta_{f}=e^{\alpha}$. Thus, our estimate of interval sizes yields

$$
\left|\left[N^{a / d}, N^{b / d}\right]\right| \in\left[e^{\alpha}\left(\frac{1}{N^{\frac{a}{d}}}-\frac{1}{N^{\frac{b}{d}}}\right)-\left(N^{\frac{b}{d}}-N^{\frac{a}{d}}\right), e^{\alpha}\left(\frac{1}{N^{\frac{a}{d}}}-\frac{1}{N^{\frac{b}{d}}}\right)+e^{\alpha}\left(\frac{1}{N^{\frac{2 a}{d}}}-\frac{1}{N^{\frac{2 b}{d}}}\right)\right] .
$$

In order to satisfy constraint (1), for a given $d$, we have to choose $\alpha$ such that

$$
\left|\left[N^{a / d}\right]\right| \geq e^{\alpha}\left(\frac{1}{N^{\frac{a}{d}}}-\frac{1}{N^{\frac{b}{d}}}\right)-\left(N^{\frac{b}{d}}-N^{\frac{a}{d}}\right) \Longleftrightarrow e^{\alpha}\left(N^{\frac{b-a}{d}}-1\right)-\left(1-N^{\frac{a-b}{d}}\right) \geq N^{1+\frac{b}{d}}
$$

Hence, we choose

$$
e^{\alpha} \approx N^{1+\frac{a}{d}} \Longleftrightarrow \alpha \approx\left(1+\frac{a}{d}\right) \cdot \ln (N) .
$$

If we now choose $d>\frac{(b+1) \beta_{f}}{\beta_{f}-1}$, then the constraint (2) holds, and for $y=1$ and $x>0$ such that $x \Delta_{f}>N^{b / d}$, constraint (3) holds as well. Thus, we obtain asymptotically the same approximation hardness result as for the case $\beta=2$.

In the case $f(n)=o(\log (n))$, the hardness of Min-DS shows a surprising phase transition and we yield the following theorem.
Theorem 6. For $\beta_{f}=2+f(n)^{-1}$ with $f(n)=o(\log (n))$, the Min-DS problem on $\left(\alpha, \beta_{f}\right)-P L G$ is in $A P X$.

Proof. We consider the case when $f(n)$ is a "slowly growing" function, namely $f(n)=o(\log (n))$. In that case, $n^{1 / f(n)} \longrightarrow \infty$ as $n \longrightarrow \infty$. For $x \Delta_{f} \leq j \leq y \Delta_{f}$, we obtain

$$
\frac{1}{j^{1+\frac{1}{f(n)}}}=\frac{1}{j} \cdot \frac{1}{j^{\frac{1}{f(n)}}} \leq \frac{1}{j} \cdot \frac{1}{\left(x \Delta_{f}\right)^{\frac{1}{f(n)}}}=\frac{1}{j} \cdot \frac{1}{x^{\frac{1}{f(n)}}} \cdot \frac{1}{e^{\alpha \cdot \frac{1}{2 f(n)+1}}},
$$

and therefore

$$
\operatorname{vol}\left(\left[x \Delta_{f}, \Delta_{f}\right]\right) \leq e^{\alpha} \cdot \ln \left(\frac{1}{x}\right) \cdot \frac{1}{x^{\frac{1}{f(n)}}} \cdot \frac{1}{e^{\alpha \cdot \frac{1}{2 f(n)+1}}},
$$

which yields the requirement $\frac{\ln (1 / x)}{x^{1 / f(n)}} \geq c \cdot e^{\alpha \cdot \frac{1}{2 f(n)+1}}$. This is equivalent to

$$
\ln \ln \left(\frac{1}{x}\right)+\frac{1}{f(n)} \cdot \ln \left(\frac{1}{x}\right) \geq \ln (c)+\frac{\alpha}{2 f(n)+1},
$$

which means the following: In order to dominate the remaining vertices of the graph with vertices from $\left[x \Delta_{f}, \Delta_{f}\right]$, we have to choose (roughly) $\ln (1 / x) \geq \alpha / 2$, i. e. $1 / x \geq e^{\alpha / 2}$. This gives the following
lower bound for the size of that interval:

$$
\left|\left[x \Delta_{f}, \Delta_{f}\right]\right| \geq e^{\alpha \cdot \frac{f(n)+1}{2 f(n)+1}} \cdot\left(e^{\frac{\alpha}{2}}-1\right)-\left(1-\frac{1}{e^{\frac{\alpha}{2}}}\right) \cdot e^{\frac{\alpha}{2+\frac{1}{f(n)}}} \geq(1-o(1)) e^{\frac{\alpha}{2} \cdot\left(1+\frac{f(n)+1}{f(n)+1 / 2}\right)} .
$$

This lower bound for the size of $\left[x \Delta_{f}, \Delta_{f}\right]$ converges to $e^{\alpha}$ as $n \rightarrow \infty$, which means there exists some $c>0$ such that $\left|\left[x \Delta_{f}, \Delta_{f}\right]\right| \geq c \cdot\left|\mathcal{G}_{\alpha, \beta_{f}}\right|$ in order to be a dominating set. Hence, each dominating set in $\mathcal{G}_{\alpha, \beta_{f}}$ is of cardinality at least $c \cdot\left|\mathcal{G}_{\alpha, \beta_{f}}\right|$ and we obtain the result.

## 10 Further Research

The further improvements on both lower and upper approximation bounds are important open questions in the area, especially the upper approximation bounds for $\beta \leq 2$. Another interesting problem concerns the approximability of PLG optimization problems on random or quasirandom instances.

## Acknowledgement

We thank Richard Schmied for a number of interesting discussions.
